Name:趙君熙

Question 1 (100 points)

Implementing Trie in Python.

Trie is a very useful data structure. It is commonly used to represent a dictionary for looking up words in a vocabulary.

For example, consider the task of implementing a search bar with auto-completion or query suggestion. When the user enters a query, the search bar will automatically suggests common queries starting with the characters input by the user.

按兩下 (或按 Enter 鍵) 即可編輯

```
YOUR CODE HERE!
# IMPLEMENTIG TRIE IN PYTHON
class TrieNode:
       def __init__(self, char:str):
          self.char = char
           self.children = {}
          self.finished = False
          self.counter = 1
class Trie(object):
       def __init__(self):
           self.root = TrieNode("")
       def insert(self, word):
           node = self.root
           for char in word:
              if char in node.children:
                  node = node.children[char]
                  new_node = TrieNode(char)
                  node.children[char] = new_node
                  node = new node
           node.finished = True
       def dfs(self, node, prefix):
           if node.finished:
              self.output.append((prefix + node.char))
           for child in node.children.values():
              self.dfs(child, prefix + node.char)
```

2023/3/13 下午3:06

```
def query(self, x):
         node = self.root
         for char in x:
            if char in node.children:
               node = node.children[char]
             else:
               return []
         self.output = []
         self. dfs (node, x[:-1])
         return self.output
# # DO NOT MODIFY THE VARIABLES
obj = Trie()
obj. insert("長庚資工")
obj. insert("長大")
obj.insert("長庚")
obj.insert("長庚")
obj.insert("長庚大學")
obj.insert("長庚科技大學")
# # DO NOT MODIFY THE BELOW LINE!
print(obj.query("長"))
# [('長庚', 2), ('長庚資工', 1), ('長庚大學', 1), ('長庚科技大學', 1), ('長大', 1)]
print(obj.query("長庚"))
# [('長庚', 2), ('長庚資工', 1), ('長庚大學', 1), ('長庚科技大學', 1)]
    ['長庚','長庚資工','長庚大學','長庚科技大學','長大']
['長庚','長庚資工','長庚大學','長庚科技大學']
```
